

## Bootstrap CV scaling: achieved vs target

Jitter + boxplot (n = 20 per level); orange diamond = target CV (perfect scaling).  
Median of boxplot should align with diamond.

Layer-2 CV scaling:  $Q_{\text{scaled}} = \mu + (Q_{\text{boot}} - \mu) * \lambda$ ,  $\lambda = CV_{\text{target}} / CV_{\text{boot}}$ .

Mean-preserving spread (Arnell 1998 Global Env. Change). Slight underachievement at high CV is expected due to the physical flow floor ( $Q \geq 0.01$  cms).
