

Bootstrap CV scaling: achieved vs target

Jitter + boxplot (n = 20 per level); orange diamond = target CV (perfect scaling).
Median of boxplot should align with diamond.

Layer-2 CV scaling: $Q_{\text{scaled}} = \mu + (Q_{\text{boot}} - \mu) * \lambda$, $\lambda = \text{CV}_{\text{target}} / \text{CV}_{\text{boot}}$.

Mean-preserving spread (Arnell 1998 Global Env. Change). Slight underachievement at high CV is expected due to the physical flow floor ($Q \geq 0.01$ cms).
